An infectious bursal disease virus (IBDV) mutant expressing virus neutralising epitopes specific for classic- and variant IBDV strains

The present invention is concerned with a classic infectious bursal disease virus (IBDV) mutant and a vaccine comprising such a classic IBDV mutant.

Infectious bursal disease virus (IBDV) is a member of the Birnaviridae family. Viruses in this family have a very similar genomic organisation and a similar replication cycle. The genomes of these viruses consist of two segments (A and B) of double-stranded (ds) RNA. The larger segment A encodes a polyprotein, which is cleaved by autoproteolysis to form mature viral proteins VP2, VP3 and VP4. VP2 and VP3 are the major structural proteins of the virion. VP2 is the major host-protective immunogen of birnaviruses, and contains the immunogenic regions responsible for the induction of virus neutralising antibodies.

For IBDV, two serotypes exist, serotype 1 and 2. The two serotypes can be differentiated by virus neutralisation (VN) tests. Serotype 1 viruses have been shown to be pathogenic to chickens, while serotype 2 IBDV only causes sub-acute disease in turkeys. Infectious Bursal disease (IBD), also called Gumboro disease, is an acute, highly-contagious viral infection in chickens that has lymphoid tissue as its primary target with a selective tropism for cells of the bursa of Fabricius. The morbidity rate in susceptible flocks is high, with rapid weight loss and moderate to high mortality rates. Chicks that recover from the disease may have immune deficiencies because of the destruction of the bursa of Fabricius, which is essential to the defence mechanism of the chicken. The IBD-virus causes severe immunosuppression in chickens younger than 3 weeks of age and induces bursal lesions in chicks up to 3 months old.

For many years the disease could be prevented by inducing high levels of antibodies in breeder flocks by the application of an inactivated vaccine, to chickens that had been primed with attenuated live IBDV vaccine. This has kept economic losses caused by IBD to a minimum. Maternal antibodies in chickens derived from vaccinated breeders prevent early infection with IBDV and diminish problems associated with immunosuppression. In addition, attenuated live vaccines have also been used successfully in commercial chicken flocks after maternal antibodies had declined.

Historically, IBD viruses consisted of only one type that is known as "classic" IBD virus. However, in the mid-1980s acute disease in flocks vaccinated with vaccines based on classic IBDV was observed, in particular in the US. It was found that this disease was caused by IBD viruses that had a different immunogenic make-up. These new viruses probably emerged as a result of genetic drift. The emergence of these so-called "variant" IBDV strains required the

design of new IBD vaccination programmes, because the classic IBDV vaccine strains could not induce an adequate cross-protection. The most important variant subtypes of serotype 1 IBDVs identified in the past were the Delaware-E, GLS, RS/593 and DS326 variants. The variant strains can be identified and distinguished from classic strains by a virus neutralisation test, a panel of monoclonal antibodies or RT-PCR.

Delaware variant-E was reported by Rosenberger et al. (Proc. 20th Natl. Meet. on Poultry Health and Condemnations; Ocean City, MD, USA, 94-101, 1985) and Snyder et al. (Avian Diseases 32, 535-539, 1985). GLS virus was isolated in the USA in 1987 and DS326 (GLS-like) was isolated in the USA in 1988 (Snyder et al., Arch. Virol. 127, 89-101, 1992 and van Loon et al. Proceedings of the International symposium on infectious bursal disease and chicken infectious anaemia, Rauischholzhausen, Germany, 179-187, 1994). Strain RS/593 (variant-E like) was also isolated in the USA, in 1993 (Snyder, et al. Proceedings of the International symposium on infectious bursal disease and chicken infectious anaemia, Rauischholzhausen, Germany, 65-70, 1994).

A panel of virus neutralising monoclonal antibodies (moab) is commonly used in the art in an antigen-capture enzyme immuno assay (AC-ELISA) to identify the various IBDV types. The reactivity pattern of these moabs with the existing IBDV strains is summarised in Table 1 below.

Table 1: The different variant IBDV strains as determined by the moab panel pattern

Strain/Moab→	8	B69	R63	10	BK9	67	57	44A1	179
Classic	+	+	+	+	-	-	-	+	+
Delaware variant (-E)	+	-	+	-	+	+	-	+	+
RS/593	+	-	-	-	-	+	-	-	+
GLS	+	-	-	+	-	-	+	+	+
DS326	+	-	-	+	-	-	+	+	-

VN moabs R63 and B69 neutralise classic IBDV strains to high titres and moab B69 specifically binds to classic strains. moab BK9 uniquely binds to Delaware variant-E strains. A positive reaction by moab 57 can be used to separate the GLS- and DS326 strains from classic- and Delaware variant strains. These and other moabs are generally used in the field to distinguish between IBDV (variant) strains by determining the reaction pattern of the panel of available moabs. The hybridomas secreting the moabs are also available from the ATCC (Rockville, USA) under the following accession numbers: R63 (HB-9490), 8 (HB-10174), B29 (HB-9746), BK-9 (HB-10157), 67 (HB-11122), 57 (HB-10156), B69 (HB-9437) and 179 (HB-10158). Variant IBDV strains and hybridomas are also available from the Collection Nationale de Cultures de Microorganismes of the Institute Pasteur, Paris, France under the following accession no.'s: DS 326 (I-910), GLS (I-792 and I-793) and moab 10 (I-2812).

Although the importance of some regions and distinct amino acids within the VP2 protein of IBDV for the antigenic variation between IBDV strains has been proposed (Vakharia et al., Virus Research 31, 265-273, 1994 and Snyder et al., Avian Diseases 38, 701-707, 1994), the mandatory presence of all the amino acids for the formation of IBDV neutralising epitopes has not been determined yet.

EP 1170302 (Akzo Nobel N.V.) discloses the preparation of a variant E IBDV mutant with improved immunogenicity against classic IBDV strains. This IBDV mutant was obtained by introducing mutations in the variant E VP2 coding region in the codons for the amino acids 253 (Gln to His), 284 (Ala to Thr) and 254 (Ser to Gly), 270 (Ala to Thr).

However, no information is disclosed therein that allows the generation of a classic IBDV mutant that also expresses a variant E- or GLS virus neutralising epitope. Such a mutant would be very useful in vaccines to induce protection against disease caused by both classic- and variant IBDV strains in the field.

In the present invention a new IBDV mutant has been constructed based on a classic IBDV by introducing mutations in the VP2 coding region such that the VP2 protein expressed by the virus comprises virus neutralising epitopes (67 or 57) typical for variant IBDVs.

Therefore, the present invention provides a classic infectious bursal disease virus mutant that expresses a VP2 protein that binds with monoclonal antibody (moab) B69, characterised in that the VP2 protein also binds with moab 67 or moab 57, secreted by hybridoma cell lines HB-9437, HB-11122 and HB-10156, deposited at the ATCC, Rockville, USA, respectively.

The IBDV VP2 protein consists of 512 amino acids and is located on the polyprotein at amino acid positions 1-512. The nucleotide sequences of (the complete segment A comprising) the VP2 coding region and the corresponding amino acid sequences of the VP2 protein of many classic IBDV strains have been determined (US 5,871,744, EP 887,412 for D78; NCBI GeneBank)

All known moabs showing virus neutralising properties, including moab B69 that is specific for classic IBDV strains, are exclusively raised against the VP2 protein and recognise conformational-dependent epitopes. Comparison of many classic- and variant VP2 amino acid sequences, in particular of variant E and GLS, are disclosed in Vakharia et al. (1994, supra) and Heine et al. (J. Gen. Virol. 72, 1835-1843, 1991). Although biological variation among virus strains exist, within the classic type of IBDV strains the amino acid sequence of the VP2 protein is strongly conserved. Amino acid homology between classic VP2 amino acid sequences varies between 98%-99.4% over the full length of the protein (based on a comparison with the VP2 amino acid sequence of IBDV strain D78). A central region within the VP2 protein was identified which contains the most variable part of VP2. This region is located at amino acid positions 206 to 350 (Bayliss et al., J. Gen. Virol. 71, 1303-1312, 1987) and amino acid homology between classic VP2 amino acid sequences within this region varies between 95.9%-97.9% (based on a comparison with the VP2 amino acid sequence of IBDV strain D78). Within this central region two hypervariable regions are identified, at positions 212-224 and 314-326, in which most of the amino acid changes between different types of IBDV strains occur (Vakharia et al., 1994, supra). Despite this, most classic IBDV strains comprise an amino acid sequence in the region 200-230 that is identical to that in VP2 of IBDV strain D78: Ser-Asp-Arg-Pro-Arg-Val-Tyr-Thr-Ile-Thr-Ala-Ala-Asp-Asp-Tyr-Gln-Phe-Ser-Ser-Gln-Tyr-Gln-Pro-Gly-Gly-Val-Thr-Ile-Thr-Leu-Phe (SEQ ID no. 19). Sequences are analyzed herein with the Wisconsin Package, version 8 (Genetics Computer Group, Madison, Wis.)

Therefore, a classic IBDV is defined herein as an isolated IBDV comprising a VP2 coding region that expresses a VP2 protein that is able to bind with moab B69.

More in particular, a classic IBDV is defined as an isolated IBDV that comprises a VP2 amino acid sequence at positions 200-230 that is the same as that of strain D78 (SEQ ID no. 19).

The reaction of a moab with an IBDV can be determined by means of an AC-ELISA that is commonly used in the art for this purpose, such as described by Snyder et al. (1992, supra) and van der Marel et al. (Dtsch. Tierartzl. Wschr. 97, 81-83, 1990).

Alternatively, the reaction of an IBDV with a moab can also be determined by means of an immunofluorescence assay as described in the Example.

A preferred classical IBDV mutant according to the invention expresses a VP2 protein that in addition to moab B69 and moab 67 binds with moab R63, secreted by hybridoma cell line HB-9490, deposited at the ATCC, Rockville, USA. The moab R63 is able to neutralise both classic- and variant E strains of IBDV.

5

The present invention for the first time identifies which amino acid residues in the context of a classic VP2 protein are required and sufficient for (i) the formation of a neutralising epitope that binds with moab R63 (classic and variant E), (ii) the additional formation of a neutralising epitope that binds with moab 67 (variant E) and (iii) for the additional formation of a neutralising epitope that binds with moab 57 (GLS).

10

The inventors prepared a number of the IBDV mutants as defined above by introducing mutations in the VP2 coding region of a classic IBDV strain (Example 1). The results obtained demonstrate that identical epitopes can be folded by different amino acid sequences, whereas other amino acid sequences fail to generate the variant epitopes. Therefore, a specific coding capacity exists for a specific epitope. A summary of the relevant amino acid sequences that are required for the appropriate folding of the 67, 57 and R63 epitopes is presented in Table 2. The information provided in Table 2 allows the skilled person to generate classic IBDV mutants capable of expressing a VP2 protein that in addition to virus neutralising epitope B69 also comprises virus neutralising epitope 67 or 57 that are specific for variant IBDV strains.

15

5

Therefore, a particularly preferred classic IBDV mutant is a mutant that binds with moab B69 and moab 67, and comprises one or more mutations in a classical VP2 coding region, such that the coding region comprises,

- (i) a codon for the amino acid at position 222 encoding serine or threonine, and
- 10 (ii) a nucleotide sequence encoding an amino acid sequence shown in any of the SEQ ID. no. 1-5 at positions 318-323.

It was found that the amino acid sequence at positions 318-323 as shown in Table 2 resulted in a proper folding of the 67 epitope only in case the amino acid at position 222 (proline) was changed to serine or threonine, implying that proper folding of the epitope is
15 influenced by amino acids located 100 positions apart.

Although the amino acid at position 330 is not critical, an advantageous IBDV mutant further comprises a codon encoding the amino acid arginine or serine at this position.

A further advantageous property of a classic IBDV mutant as defined above is that such a mutant also expresses a VP2 protein having the required amino acid sequence for the proper folding of the R63 virus neutralising epitope. It is demonstrated in the Table 2 and Example 1 that an IBDV that expresses a VP2 protein having an amino acid sequence at positions 318-323 as shown in any of the SEQ ID no. 14-15 and 17-18 (in addition to an serine or threonine at position 222) displays epitope R63 but fails to display epitope 67.

Based on the data summarized in Table 2, a further particularly preferred classic IBDV mutant that binds with moab B69 and moab 57, is a mutant that comprises one or more mutations in a classical VP2 coding region, such that the coding region comprises,

- (i) a nucleotide sequence encoding an amino acid sequence shown in any of the SEQ ID. No. 6-9 at positions 318-323, and, preferably,
- (ii) a codon for the amino acid at position 222 encoding proline, serine or threonine.

For this mutant the amino acid position 222 is not critical, as both amino acid proline (present in classic VP2) and serine or threonine (present in variant E) VP2 allowed the proper folding of the 57 epitope. With regard to position 330 no preference exists between arginine and serine in case the amino acid sequence at positions 318-323 is as shown in SEQ ID no. 6, but is preferably arginine in case the amino acid sequence at positions 318-323 is as shown in any of the SEQ ID no. 7-9.

Therefore, an advantageous classic IBDV mutant is a mutant that binds with moab B69 and moab 57, and further comprises a codon for the amino acid at position 330 encoding,

- (i) arginine or serine, in case the coding region comprises a nucleotide sequence encoding an amino acid sequence shown in SEQ ID. No. 6 at positions 318-323, or
- (ii) arginine, in case the coding region comprises a nucleotide sequence encoding an amino acid sequence shown in SEQ ID. No. 7-9 at positions 318-323.

A further surprising observation made by the inventors is that an exchange of an amino acid in the VP2 coding region at positions 318-323 of a classic IBDV strain results in a decrease of the growth properties of such mutants. Such mutants display an attenuated phenotype for chickens and can advantageously be used as vaccine candidates with improved safety properties, in particular in vaccines that are administered via the in ovo route. Therefore, the present invention also provides a classic IBDV mutant that comprises one or more mutations in a classic VP2 coding region, such that the coding region comprises a nucleotide sequence encoding an amino acid sequence at positions 318-323 that is different from the natural amino acid sequence Gly-Gly-Gln-Ala-Gly-Asp (SEQ ID no. 1). Preferably, these classic IBDV mutants comprise an amino acid sequence at these positions as shown in

any of the SEQ ID No. 2-9 and 11-18, optionally, together with an amino acid at position 222 and/or 330 as defined above.

5 A classic IBDV mutant according to the invention can be prepared by introducing the required mutations in a VP2 coding region derived from any classic IBDV strain isolatable from the field or used in vaccines. Suitable IBDV strains include the well-known IBDV strains present in commercially available vaccines, such as D78, PBG98, 228E and 89-03 (Intervet International B.V.). IBDV strain D78 (US patent no. 4,530,831) is also available from the ATCC under accession no. VR-2041. The nucleotide sequence of the complete segment A of strain
10 D78, including the VP2 coding region, and the amino acid sequence of the corresponding (poly)protein is disclosed in US patent no. 5,871,744 and EP application 887,412.

In particular, a classic IBDV mutant is provided that comprises one or more mutations in a VP2 coding region of IBDV strain D78.

15 A further preferred classic IBDV mutant according to the present invention comprises the complete genetic backbone of the segment A of a classic IBDV strain, including the mutated classic VP2 coding region as described above. More in particular, a classic IBDV mutant as defined above is derived from IBDV strain D78.

However, a classic IBDV mutant according to the invention can also be based on the genetic backbone of a variant IBDV strain, such as a variant E or GLS strain. In such a
20 "chimeric" classic IBDV mutant, the VP2 coding sequences on the genetic backbone of segment A of a variant IBDV strain are replaced by the corresponding, relevant classic VP2 coding sequences that additionally comprise the desired mutations that are responsible for the new variant epitopes on the classic IBDV mutant.

25 The generation of a classic IBDV mutant according to the invention can be achieved by means of the recently established infectious cRNA system for IBDV (Mundt and Vakharia, Proc. Natl. Acad. Sci. USA 93, 11131-11136, 1996). This reverse genetics system provides the possibility to introduce mutations in the RNA genome of the IBDV. The most important step in this reverse genetics system is to provide full length cDNA clones of the segments A and B of the IBDV, including the nucleotides of the 5'- and 3'- ends of both these segments.
30 After cloning procedures, the full length sequences of segment A and B are operably linked to a promoter which is able to bind a DNA dependent RNA polymerase, such as the T7, SP6 or T3 polymerase, the T7 promoter being preferred. The DNA dependent polymerase is able to describe viral cRNA from full length cDNA clones of segment A and B, respectively. This
35 cRNA is able to induce replication of the virus and the isolation of viable virus. This procedure can be performed with every natural occurring IBDV.

Reverse genetics systems have been described for various IBDV strains, such as D78 (Yao et al., J. Virol. 72, 2647-2657, 1998), strain HK46 (Lim et al., J. Virol. 73, 2854-2862, 1999), CEF 94 (Boot et al., Virology 265, 330-341, 1999) and UK661 (van Loon et al., J. Gen. Virol. 83, 121-129, 2002).

5 The desired mutations can be introduced into the IBDV genome by means of methods generally known in the art for this purpose. In particular, the mutation(s) are introduced by means of site-directed mutagenises. Methods for introducing a mutation in the IBDV genome are described herein, but are also generally used in the art (Mundt and Vakharia, 1996, supra; Yao et al., J. Virology 72, 2647-2654, 1998; Mundt et al., 1999, supra; EP patent application
10 no. 1170302; Current Protocols in Molecular Biology, eds.: F. M. Ausubel et al., Wiley N.Y., 1995 edition, pages 8.5.1.-8.5.9. and Kunkel et al. in Methods in Enzymology vol. 154, 376-382, 1987).

The numbers used herein to indicate the amino acid positions refer to numbering of the amino acids in the IBDV polyprotein as commonly used in the art. The numbers indicating the
15 nucleotide positions are based on the complete nucleotide sequence of the segment A of the IBDV genome as described by Mundt and Müller (J. Gen. Virol. 77, 437-443, 1995; NCBI accession number X 84034).

The segment B of a classic IBDV mutant according to the invention can be derived from any IBDV strain, preferably from a classic IBDV strain, most preferably from strain D78 or P2
20 (US patent 5,871,744 and EP patent application no. 887412).

As demonstrated in the Example, the classic IBDV mutant according to the invention displays an immunogenic make-up that is not observed before for classic IBDV strains. The new classic IBDV mutant may form the basis of a new type of IBDV vaccine that can
25 effectively protect poultry against disease conditions resulting from the infection by both classic- and variant IBDV strains. Therefore, another aspect of this invention is a vaccine for use in the protection of poultry against disease caused by IBDV infection, characterised in that the vaccine comprises a classical IBDV mutant as defined above, together with a pharmaceutical acceptable carrier or diluent.

30 The classical IBDV mutant can be incorporated into the vaccine as live attenuated or inactivated virus.

A vaccine according to the invention can be prepared by conventional methods such as for example commonly used for the commercially available live- and inactivated IBDV vaccines. Briefly, a susceptible substrate is inoculated with a classical IBDV mutant according
35 to the invention and propagated until the virus replicated to a desired infectious titre after

which IBDV containing material is harvested, optionally inactivated, and mixed with a pharmaceutical acceptable carrier or diluent.

Every substrate which is able to support the replication of IBDVs can be used to prepare a vaccine according to the present invention, including primary (avian) cell cultures, such as chicken embryo fibroblast cells (CEF) or chicken embryo liver cells (CEL), mammalian cell lines such as the VERO cell line or the BGM-70 cell line, or avian cell lines such as QT-35, QM-7 or LMH. Usually, after inoculation of the cells, the virus is propagated for 3-14 days, after which the cell culture supernatant is harvested, and if desired filtered or centrifuged in order to remove cell debris.

10 The classical IBDV mutant can also be propagated in embryonated chicken eggs.

If desired, attenuation of the classical IBDV can be obtained by standard serial passaging of the virus in cell cultures, for example in the primary cell cultures or established cell lines mentioned above (Bayyari et al., Avian Diseases 40, 516-532, 1996; Tsal et al., Avian diseases 36, 415-422, 1992).

15 Alternatively, the classical IBDV can be propagated in vivo in infected chickens followed by the isolation of the bursa of Fabricius from these infected animals, mixing it with diluent and homogenizing the mixture. IBDV propagated in this way commonly forms the basis of an inactivated vaccine.

The vaccine according to the invention containing the live virus can be prepared and marketed in the form of a suspension or in a lyophilised form and additionally contains a pharmaceutically acceptable carrier or diluent customary used for such compositions. Carriers include stabilisers, preservatives and buffers. Suitable stabilisers are, for example SPGA, carbohydrates (such as sorbitol, mannitol, starch, sucrose, dextran, glutamate or glucose), proteins (such as dried milk serum, albumin or casein) or degradation products thereof. Suitable buffers are for example alkali metal phosphates. Suitable preservatives are thimerosal, merthiolate and gentamicin. Diluents include water, aqueous buffer (such as buffered saline), alcohols and polyols (such as glycerol).

25 If desired, the live vaccines according to the invention may contain an adjuvant. Examples of suitable compounds and compositions with adjuvant activity are the same as mentioned below.

30 Although administration by injection, e.g. intramuscularly, subcutaneously or in ovo of the live vaccine according to the present invention is possible, the vaccine is preferably administered by an inexpensive mass application route commonly used for IBDV vaccination. For IBDV vaccination this route includes drinking water, spray and aerosol vaccination.

Alternatively, the present invention provides a vaccine comprising the variant IBDV in an inactivated (killed) form. An advantage of an inactivated IBDV vaccine is the high levels of protective antibodies of long duration that can be obtained.

5 The aim of inactivation of the viruses harvested after the propagation step is to eliminate reproduction of the viruses. In general, this can be achieved by chemical or physical means well known in the art.

A vaccine containing the inactivated variant IBDV can, for example, comprise one or more of the above-mentioned pharmaceutically acceptable carriers or diluents suited for this purpose.

10 Preferably, an inactivated vaccine according to the invention comprises one or more compounds with adjuvant activity. Suitable compounds or compositions for this purpose include aluminium hydroxide, -phosphate or -oxide, oil-in-water or water-in-oil emulsion based on, for example a mineral oil, such as Bayol F® or Marcol 52® or a vegetable oil such as vitamin E acetate, and saponins.

15 The vaccine according to the invention comprises an effective dosage of the classical IBDV mutant as the active component, i.e. an amount of immunising IBDV material that will induce immunity in the vaccinated birds against challenge by a virulent virus. Immunity is defined herein as the induction of a significant higher level of protection in a population of birds after vaccination compared to an unvaccinated group.

20 Typically, the live vaccine according to the invention can be administered in a dose of 10^0 - 10^9 TCID₅₀ per animal, preferably in a dose ranging from 10^3 - 10^6 TCID₅₀ per animal. Inactivated vaccines may contain the antigenic equivalent of 10^6 - 10^{10} TCID₅₀ per animal.

Inactivated vaccines are usually administered parenterally, e.g. intramuscularly or subcutaneously.

25 Although, the IBDV vaccine according to the present invention may be used effectively in chickens, also other poultry such as turkeys, guinea fowl and partridges may be successfully vaccinated with the vaccine. Chickens include broilers, pullets, reproduction stock and laying stock.

30 The age of the animals receiving a live or inactivated vaccine according to the invention is the same as that of the animals receiving the conventional live- or inactivated IBDV vaccines. For example, broilers (free of maternally derived antibodies-MDA) may be vaccinated at one-day-old or in ovo, whereas broilers with high levels of MDA are preferably vaccinated at 2-3 weeks of age. Laying stock or reproduction stock with low levels of MDA may be vaccinated at 1-10 days of age followed by booster vaccinations with inactivated
35 vaccine on 6-12 and 16-20 weeks of age.

The invention also includes combination vaccines comprising, in addition to the classical IBDV mutant described above, one or more vaccine components of other pathogens infectious to poultry.

5 Preferably, the combination vaccine additionally comprises one or more vaccine strains of Mareks Disease virus (MDV), infectious bronchitis virus (IBV), Newcastle disease virus (NDV), egg drop syndrome (EDS) virus, turkey rhinotracheitis virus (TRTV) or reovirus.

EXAMPLES

Example 1

5 **Preparation of classic IBDV mutants and determination of monoclonal antibody reactivity**

Material and Methods

10 **Generation of mutated segment A**

For site directed mutagenesis experiments pD78A (Mundt and Vakharia, supra, 1996; EP application 887412) was used. To this end pD78A was EcoRI/KpnI cleaved and the segment A containing fragment was ligated into appropriately cleaved pBlueScript KS+ to obtain pSK+-D78A. After preparation of single stranded DNA site directed experiments were performed according to Kunkel et al. (supra, 1987) using oligonucleotides as specified in Table 3. Oligonucleotides Mut 1, Mut 2, Mut3, Mut4, Mut5, Mut6, Mut7, Mut8, Mut9, Mut10, Mut11 were used to generate mutated plasmids pMut1, pMut2, pMut3, pMut4, pMut5, pMut6, pMut7, pMut8, pMut9, pMut10, and pMut11, respectively. Using this eleven mutated plasmids single stranded DNA was prepared and used together with single stranded DNA of pSK+-D78A in site directed mutagenesis experiments. These experiments were performed with one (P222S or R339S) or two oligonucleotides (P222S and R339S) in one experiment to obtain one or two exchanges of base triplets. Obtained mutagenised plasmids (shown in Table 4) were sequenced and used for further experiments.

25 **Transfection of cRNA, Immunofluorescence assays and passaging of generated virus**

For *in vitro* transcription plasmids containing pD78A and mutagenised plasmids were linearized by cleavage with BsrG I. pP2B (Mundt & Vakharia, supra, 1996; EP application 887412) was linearized using Pst I. Further treatment of linearized DNA, transcription and transfection of RNA into BHK 21 cells were carried out as described by Mundt (J. Gen. Virol. 80, 2067-2076, 1999). For immunofluorescence assay BHK21 cells grown in 24 well tissue culture plates were transfected and 24h after transfection acetone/ methanol (50%/50%) fixed for 5 min and dried. Fixed cells were incubated with monoclonal antibodies 67, B69, 57, R63 and rabbit anti-IBDV serum (Mundt et al., J. Gen. Virol. 76, 437-443, 1995), respectively, diluted in phosphate buffered saline (PBS) for 30 min and rinsed thrice with PBS. Cells were now incubated for 30min in PBS diluted DTAF- conjugated goat anti-rabbit IgG or DTAF-conjugated goat anti-mouse IgG (Dianova, Hamburg, Germany) followed by

three washes using PBS and one wash with distilled water. After air drying cells were mounted in 2.5% 1.4.-Diazobicyclo(2.2.2.)-octane (DABCO, Sigma, Deisenhofen, Germany) containing PBS with 90% glycerol. Fluorescence was visualised using a immerse fluorescence microscope.

- 5 For passaging of generated virus BHK21 cells grown in 6 well tissue culture plates were transfected in parallel to the transfection experiments in 24 well tissue culture plates and incubated for 24h – 48h. After freeze/thaw at -70° for at least one hour obtained supernatant was centrifuged at $6400 \times g$ for 10min and passaged onto QM cells grown in 25cm^2 tissue culture flask until CPE was visible. Supernatant was obtained as described
- 10 above, aliquoted and stored at -70°C . For analysis of viability and presence of reactivity with the mmAb QM-cells grown in 24 well tissue culture plates were infected with one aliquot and incubated for 24h. Immunofluorescence assay was performed as described above.

15 **Growth analysis of generated virus in cell culture**

- To monitor growth CEC grown in 24 well tissue culture plate were infected with selected IBDV at a MOI of 1 for 1 h at 37°C . Thereafter, inoculum was removed, cells were washed with medium and 1ml medium was added. Supernatants were harvested separately immediately thereafter (0 h), and after 8, 12, 16, 24 and 36 h of incubation at 37°C and
- 20 stored at -70°C . Virus titers were obtained by determination of TCID₅₀ using QM-cells (Quail muscle cells) grown in 96 well tissue culture plates. To this end supernatants were thawed and titrated in log₁₀ steps. 100 μl each of the appropriate dilution was pipetted into four wells of a tissue culture plate followed by addition of 100 μl QM cells suspension (10^6 cells/ml). The plates were incubated at 37°C . After five days wells with CPE were
- 25 counted as positive and TCID₅₀ was determined following Spaerman (Brit. J. Psychol., 2, 227-242, 1908) and Karber (Arch. Exp. Path. Pharmacol., 162, 480-487, 1931). Average values and standard deviations of three independent experiments were calculated.

30 **Results**

Influence of the exchange of amino acids in the variable region of VP2 on the reactivity of monoclonal antibodies

- Amino acids located in the sequence of strain D78 at position 222 (proline), 318 (glycine),
- 35 321 (alanine), and 323 (aspartate) were exchanged to amino acids serine, threonine

(P222S, P222T), aspartate, asparagine (G318D, G318N, glutamate (A321E), and glutamate (D323E), respectively, in different combinations (see Table 4). Exchange of proline in position 222 to serine resulted in an additional reactivity of moab 67 if the aa sequence of aa from position 318 to 323 was of following combinations: GGQAGD, DGQAGD, 5 DGQAGE, GGQAGE, NGQAGE. The remaining combinations of the aa sequence from position 318 to 323 (DGQEGD, DGQEGE, GGQEGD, GGQEGE, NGQAGD, NGQEGD, NGQEGE) seems to prevent the folding of the epitope characterized by moab 67 even if proline at position 222 was exchanged to serine. Binding of moab 57 was detected after exchange of aa 321 from alanine to glutamate independent if amino acid 222 (proline), 318 10 (glycine), and 323 (aspartate). But the exchange of arginine to serine at position 330 influenced the presence of the 57 epitope. Here if the performed exchange (R330S) was performed in presence of the combinations DGQEGD, NGQEGD, and NGQEGE, respectively, no reactivity with moab 57 was detected after co-transfection experiments. In contrast, the exchange R330S showed no influence on the reactivity with moab 57 in 15 presence of the combination GGQEGD. The presence of reactivity of moab 57 and R63 excluded each other in the performed experiments since if the 57 epitope was present the R63 epitope was absent. Furthermore reactivity with moab R63 after co-transfection experiments was recorded after usage of plasmids encoding combinations GGQAGD, DGQAGD, DGQAGE, GGQAGE, NGQAGD, and NGQAGE from aa 318 to 323 located in 20 the VP2 region independent if aa 222 (proline) or aa 330 (arginine) was exchanged. Translated protein of cRNA of plasmids encoding the amino acid sequence DGQEGE or GGQEGE from position 318 to 323 of the polyprotein gene reacted only with the moab 69. Here also the exchange of aa 222 and/or 330 seems to have no influence on the reactivity. After all transfection experiments cells were freezed/thawed and the obtained supernatant 25 was passaged. In each case viable virus was generated indicating that the performed mutagenised amino acids had no influence on viability and infectivity of cell culture of the virus.

Analysis of growth in cell culture

30 To test if amino acid exchange influence the growth of mutated virus several mutated IBDV (D78, Mut1, Mut2, PS-D78, PS-Mut1, PS-Mut2, Mut 10, Mut11) were analysed. To this end generated IBDV were selected which contain the same reactivity pattern with the used panel of moab. As shown in Figure growth of virus was influenced by exchange of amino acids in certain regions. Exchange of amino acid 222 from proline to serine showed no influence in 35 growth in cell culture. In contrast, exchange in the region from amino acid 318 to 323 influenced the growth of the investigated mutants. These mutants growth to lower titers at

16

all time points investigated indicating that the region from aa 318 to aa323 is of importance for growth in cell culture.

CLAIMS

- 5 1 A classic infectious bursal disease virus (IBDV) mutant that expresses a VP2 protein that binds with monoclonal antibody (moab) B69, characterised in that the VP2 protein also binds with moab 67 or moab 57, secreted by hybridoma cell lines HB-9437, HB-11122 and HB-10156, deposited at the ATCC, Rockville, USA, respectively.
- 10 2 A classic IBDV mutant according to claim 1, characterised in that the VP2 protein binds with moab B69, moab 67 and moab R63, secreted by hybridoma cell line HB-9490, deposited at the ATCC, Rockville, USA.
- 15 3 A classic IBDV mutant according to claim 1, characterised in that the mutant comprises one or more mutations in a classic VP2 coding region, such that the coding region comprises,
 (i) a codon for the amino acid at position 222 encoding serine or threonine, and
 (ii) a nucleotide sequence encoding an amino acid sequence shown in any of the SEQ ID. No. 1-5 at positions 318-323.
- 20 4 A classic IBDV mutant according to claim 3, characterised in that the coding region comprises a codon for the amino acid at position 330 encoding arginine or serine.
- 25 5 A classic IBDV mutant according to claim 1, characterised in that the mutant comprises one or more mutations in a classic VP2 coding region, such that the coding region comprises,
 (i) a nucleotide sequence encoding an amino acid sequence shown in any of the SEQ ID. No. 6-9 at positions 318-323, and, preferably,
 (ii) a codon for the amino acid at position 222 encoding proline, serine or
30 threonine.
- 35 6 A classic IBDV mutant according to claim 5, characterised in that the coding region comprises a codon for the amino acid at position 330 encoding,
 (i) arginine or serine, in case the coding region comprises a nucleotide sequence encoding an amino acid sequence shown in SEQ ID. No. 6 at positions 318-323, or

(ii) arginine, in case the coding region comprises a nucleotide sequence encoding an amino acid sequence shown in SEQ ID. No. 7-9 at positions 318-323.

7 A classic IBDV mutant according to claims 1-6, characterised in that the mutant comprises one or more mutations in a VP2 coding region of IBDV strain D78.

8 A classic IBDV mutant according to claims 1-7, characterised in that the mutant comprises a genomic segment A of a classic IBDV, preferably of IBDV strain D78.

9 A vaccine for use in the protection of poultry against disease caused by IBDV infection, characterised in that the vaccine comprises a classic IBDV according to claims 1-8, together with a pharmaceutical acceptable carrier or diluent.

10 A vaccine according to claim 9, characterised in that the classic IBDV mutant is in a live form.

11 A vaccine according to claim 9 or 10, characterised in that the vaccine further comprises one or more vaccine components of other pathogens infectious to poultry.

12 A vaccine according to claims 9-11, characterised in that the vaccine comprises an adjuvant.

13 A method for the preparation of a classic IBDV mutant according to claims 1-8, characterised in that the classic IBDV mutant is propagated in a cell culture and subsequently harvested from the cell culture.

14 A method for the preparation of a vaccine according to claims xx, characterised in that a classic IBDV mutant according to claims 1-8 is mixed with a pharmaceutical acceptable carrier or a diluent.

15 A method for the protection of poultry against disease caused by IBDV infection, characterised in that the vaccine according to claims 9-12 is administered to the animals.

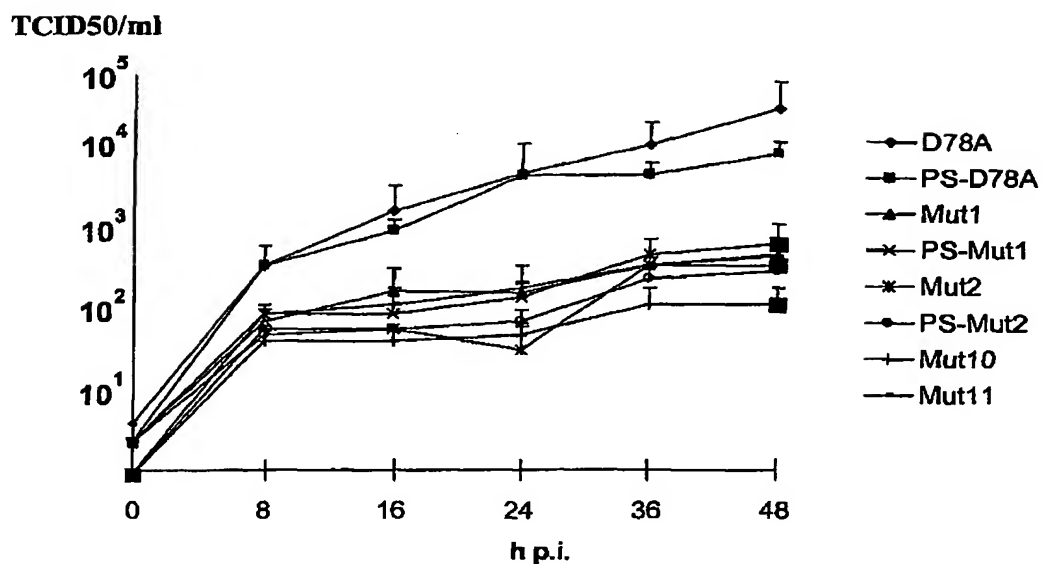

ABSTRACT

The present invention provides a classic IBDV mutant that additionally comprises virus neutralising epitopes 67 (specific for variant-E IBDV) or 57 (specific for GLS IBDV).
